Abstract
Conductivities of Sn(IV) doped lanthanum silicates apatite as an electrolyte for intermediate temperature solid oxide fuel cells (ITSOFCs) have been examined. Dense ceramic pellet of La_{9.33}Si_{6-x}Sn_xO_{26} (x: 0.1; 0.3; 0.5) have been prepared by sintering at 1773K for 3 hours. The sample La_{9.33}Si_{6}Sn_{0.5}O_{26} shows higher conductivities than comparable La_{9.33}Si_{5.5}Sn_{0.1}O_{26} and La_{9.33}Si_{5.5}Sn_{0.0}O_{26}, samples indicating the importance of dopant concentration. Low activation energy of all samples (E_a < 1.1 eV) indicate that the Sn(IV) doped electrolytes are good conductors that can be used for ITSOFCs.

Keywords: Doped lanthanum silicates apatite, ITSOFCs, electrolyte.

Introduction
Lanthanum silicates with an apatite structure are considered as potential candidates for SOFCs operated at intermediate temperature, owing to its high ionic conductivity of 2.95 × 10^{-4} S cm^{-1} at 500°C and low activation energy of about 0.8 eV. The open structure of lanthanum silicate apatite suggests that this material should be appropriate for the electrolyte applications for intermediate temperature SOFCs.

The computer modeling studies have indicated the importance of the silicate substructure in aiding the motion of the oxide ions down the channels in the apatite-type oxide ion conductors. The structure of lanthanum silicate apatite is highly tolerance to cation and anion doping. In P63/m, La_{9.33}Si_{6-x}Sn_xO_{26} has O1, O2, O3, O4 atoms and the interstitial oxygen O5, located at site [12i; (x, y, z)] near the hexagonal channel proposed from atomistic simulation.

Numerous cationic doping were preparation at the Si site, this strategy is helpful to increase the conductivity of apatite lanthanum silicates. Substitution of cations with a relatively low valence, Mg^{2+}, Ca^{2+}, Ga^{3+} has a beneficial effect on conductivity. Doping of cations with a same valence such as Sn^{4+} relative few studies was reported.

Lanthanum silicate apatite doped with tetravalent Sn^{4+} cations at the Si^{4+} site (La_{10}Si_{5.5}Sn_{0.5}O_{26.75}) exhibits a similar total conductivity to undoped La_{10}Si_{6}O_{27}. Few studies were carried out on the influence of doping Sn^{4+} with different concentration. In this work, La_{9.33}Si_{6-x}Sn_xO_{26} (x: 0.1; 0.3; 0.5) lanthanum silicate apatites have been prepared by hydrothermal reaction as a first step. Then, the structural characterization of prepared materials has been performed with XRD and refinement techniques using Rietica software. Finally, conductivity properties of the lanthanum silicate apatite have been investigated by complex impedance spectroscopy.

Material and Methods
Synthesis of Sn(IV) doped lanthanum silicates apatite: To prepare the series Sn(IV) doped lanthanum silicates apatite (La_{9.33}Si_{6-x}Sn_xO_{26}; x: 0.1; 0.3; 0.5) were prepared from La_2O_3, 99.999% (Aldrich), Na_2SiO_3, 97% (Sigma), and SnO_2, 99.999% (Sigma-Aldrich). The reactants in the correct stoichiometric ratio were intimately mixed and hydrothermally synthesized at 503 K for 72 h. Phase purity was then examined using powder X-Ray diffraction (Rigaku SmartLab) using Cu-Kα radiation. Ionic conductivity was measured using LCR (GW Instek 61056) at 873 – 973 K and a frequency range of 20 Hz – 5 MHz on the pellet sample that was obtained by applying 6000 kg cm^{-2} pressure followed by sintering at 1773 K for 3 hours.

Results and Discussion
Fig. 1 shows the XRD patterns of apatite-type La_{9.33}Si_{6}O_{26} ceramics and Sn(IV)-doped series, La_{9.33}Si_{6-x}Sn_{x}O_{26} (x: 0.1; 0.3; 0.5) ceramics. The main diffraction peaks of various ceramics are in agreement with the standard XRD diffraction of La_{9.33}Si_{6}O_{26} (ICSD No. 158963).

The lattice parameters of La_{9.33}Si_{5.5}Sn_{0.1}O_{26}, La_{9.33}Si_{5.5}Sn_{0.3}O_{26} and La_{9.33}Si_{5.5}Sn_{0.5}O_{26} ceramics are listed in table 1. All the ceramics consist only of a hexagonal apatite structure with a space group P6_3/m, however, all ceramics are composed of a hexagonal apatite structure and a small amount of second phase La_2SiO_5, which is usually characterized by the presence of typical peaks at 20 values of about 15.48° and 47.26°. Previous studies also reported on the difficulty to eliminate La_2SiO_5 phase in lanthanum silicates under most of synthesis and sintering conditions. It is very difficult to find a correlation between Sn content, and the lattice parameter changes. Phase of La_{9.33}Si_{5.5}Sn_{0.1}O_{26} has highest lattice parameter.

The reported cell parameter data are similar with each other, no significant shift is observed in all diffraction pattern of
Sn(IV) doped apatite, as expected size of dopant and host cation. SEM micrograph of La$_{9.33}$Si$_6$O$_{26}$ ceramics and Sn(IV)-doped series of (La$_{9.33}$)$_x$Si$_6$-xO$_{26}$ (x : 0.1 ; 0.3 ; 0.5) ceramics (Fig. 2) show grain and grain boundary region as a function of Sn$^{4+}$content.

The homogeneity, porosity and the average grain size decreased when composition of Sn$^{4+}$is 0.1 and 0.3 but grain size increased at Sn$^{4+}$ 0.5. It is due to effect of the Sn$^{4+}$ content to homogeneity and porosity.

In general, the electrical conductivities of polycrystalline materials are greatly influenced by their microstructures i.e. the properties of grain and grain boundary. AC impedance spectroscopy is widely employed to obtain information related to the electrical behavior of both the bulk (grain interiors) and the grain boundaries. A typical impedance plot for La$_{9.33}$Si$_6$O$_{26}$, La$_{9.33}$Si$_5$Sn$_{0.1}$O$_{26}$, La$_{9.33}$Si$_5$Sn$_{0.3}$O$_{26}$, and La$_{9.33}$Si$_5$Sn$_{0.5}$O$_{26}$ is shown in fig. 3.

There is no difference in the curves seen in all four impedance spectra, all dominated by the bulk phase response curve, the bulk resistance globally increases with porosity$^{12}$. Base on the observations of SEM micrographs (Fig. 2), it is very difficult to find a correlation between Sn content, morphology and the resistance of the bulk phases.

Table 2 listed conductivity of La$_{9.33}$Si$_5$Sn$_{0.1}$O$_{26}$, La$_{9.33}$Si$_5$Sn$_{0.3}$O$_{26}$, and La$_{9.33}$Si$_5$Sn$_{0.5}$O$_{26}$ at 873-973 K. Compared with non-doped apatite, all Sn(IV) doped apatites have lower conductivity at all measuring temperatures according to a previous study$^7$. Meanwhile, the order of conductivity of Sn(IV) doped apatites from large to small is as follows: La$_{9.33}$Si$_5$Sn$_{0.5}$O$_{26}$ > La$_{9.33}$Si$_5$Sn$_{0.3}$O$_{26}$ > La$_{9.33}$Si$_5$Sn$_{0.1}$O$_{26}$, and La$_{9.33}$ Si$_5$Sn$_{0.5}$O$_{26}$. It is hard to determine correlation between the change in conductivity to the change of lattice parameters, as well as the ceramic density. Computer simulations technic are required to predict the effect of changes in lattice and morphological parameters on the conductivity of Sn(IV) doped apatite.

Fig. 4 presents the Arrhenius plots of total conductivity of La$_{9.33}$Si$_6$-xSn$_x$O$_{26}$ (x : 0.1 ; 0.3 ; 0.5) ceramics. The straight lines are well fitted to the Arrhenius equation which demonstrates that the diffusion process of oxide ions is thermally activated in the range of 873–973 K, which also indicates that the ionic diffusion process is thermally activated.

The activation energy represents the minimum energy required for the oxide-ion diffusion process to happen. The values of activation energy $E$ and pre-exponential factor $\sigma_0$ can be determined from the slope and the intercept of the linear. It is in the logarithmic form of the Arrhenius equation for each composition respectively. Activation energy of total conductivity of La$_{9.33}$Si$_5$-xSn$_x$O$_{26}$ (x = 0.1; 0.3; 0.5) ceramics is shown in Table 3.

All values of the activation energy were smaller than 1.1 eV. Low activation energy (<1.1 eV) indicates that La$_{9.33}$Si$_6$-xSn$_x$O$_{26}$ (x = 0.1; 0.3; 0.5) conductivity at 873–973 K is generated from the interstitial oxygen ion migration$^{13}$. These results indicate that both the composite material are good ionic conductors as electrolyte of solid oxide fuel cell.

As seen in table 3 and fig. 4, the activation energies of La$_{9.33}$Si$_6$-xSn$_x$O$_{26}$ (x = 0.1; 0.3; 0.5) are lower than those of La$_{9.33}$Si$_6$O$_{26}$. On the other hand, Sn dopant decreases the activation energies, although it will not increase their conductivity.

Conclusion
Sn(IV) doped Apatite-type La$_{9.33}$Si$_6$-xSn$_x$O$_{26}$ (x: 0.1; 0.3; 0.5) ceramics were prepared via hydrothermal route. All the ceramics consist only of a hexagonal apatite structure with a space group $P6_3/m$; however, ceramics are composed of second phase La$_2$SiO$_5$. The highest total conductivity was obtained from La$_{9.33}$Si$_6$-xSn$_x$O$_{26}$ with $x = 0.3$.
